Department of Electrical & Computer Engineering

LAB REPORT			
Course Code: EEE11	11.3		
Course Title: Analog	Electronics I		
Course Instructor:	MS. SYEDA SARITA HASSAN		
Experiment Number:	: 02		
Diode rectifier circuits			

Experiment Name:

Experiment Date: 10/11/2021

Date of Submission: 19/11/2021

Section: 03

Group Number: 10

Submitted To: MD. AL – AMIN BHUIYAN

Submitted By: Both Score

Student Name	ID	
1. Hasibur Rahman Ridoy	1812046042	
2. Showvik Saha	1822177042	

Name of the Experiment: Diode rectifier circuits

Objectives: Study of various rectifier circuits.

Apparatus:

- 1. 4xp-n junction diode.
- 2. 1x10k Register.
- 3. $1 \times 0.22 \mu F$ capacitor.
- 4. $1 \times 10 \mu F$ capacitor.
- 5. 1x oscilloscope.
- 6. Digital Multimeter.
- 7. Chords and Wires.

Theory: Rectification is the conversion of alternating current to direct current. It is also the one-way flow of electric charge. When AC voltage is applied it allows a half cycle during its forward bias condition, the other half cycle remains clipped off.

There are two major types of rectifiers -

- 1. Half wave rectifier.
- 2. Full wave rectifier.

<u>Half wave rectifier:</u> It's the simplest kind of rectifier. It converts only the half cycle of AC into DC. Another half remains clipped off.

<u>Full wave rectifier:</u> It has both positive and negative half cycles of the AC into DC. It provides double output voltage.

Circuit Diagram:

Experimental Procedures: First of all, we need to make the circuit by using those equipment. Then we check the output and input voltage. In the half wave rectifier We check the voltage across $10k\Omega$ register. Then

gradually we added $0.22\mu F$ and $10\mu F$ capacitor. Now observe the graph. After this we remake the circuit for a full wave rectifier. First we check the voltage drop across the $10\mu K$ register then gradually add $0.22\mu F$ and $10\mu F$ capacitor and observe how the graph is behaving. Finally we vary the frequency from 10khz to 100hz and observe the graph's behaviour.

Simulation:

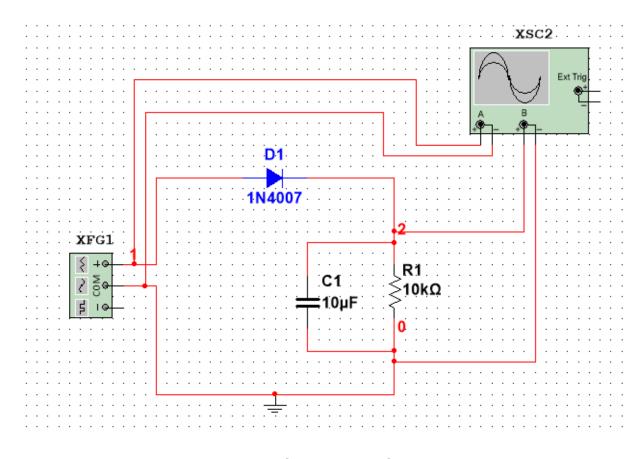

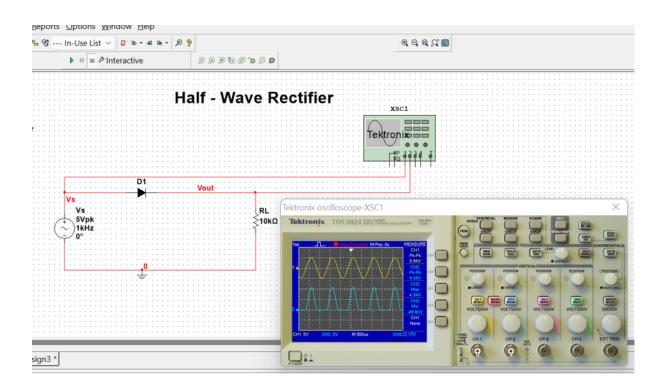

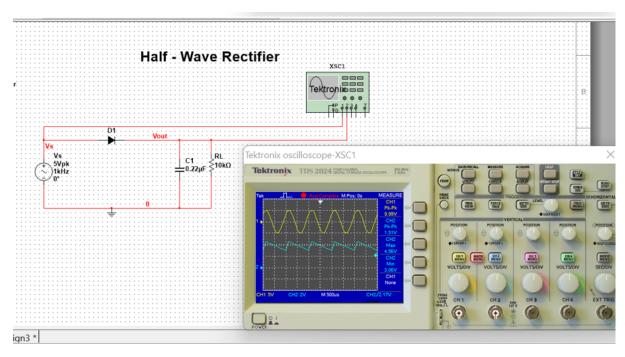

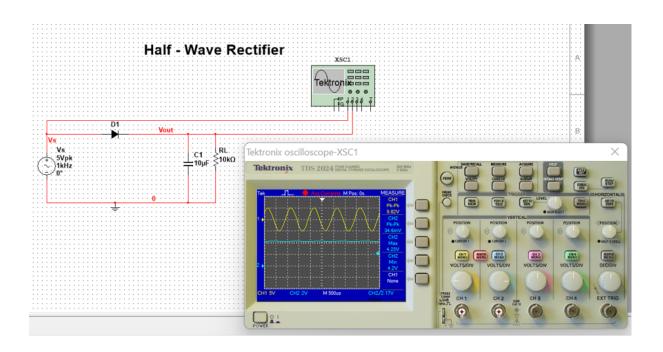

Fig: Half wave rectifier

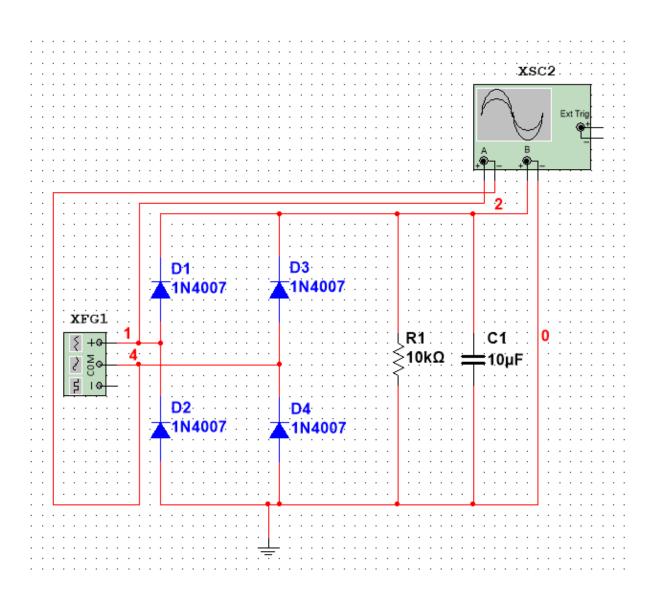

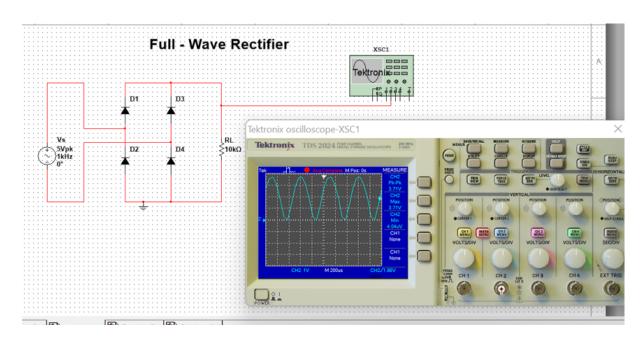

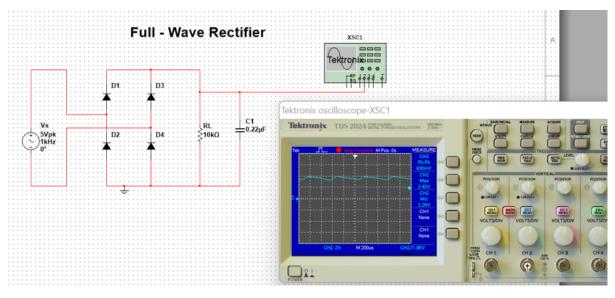

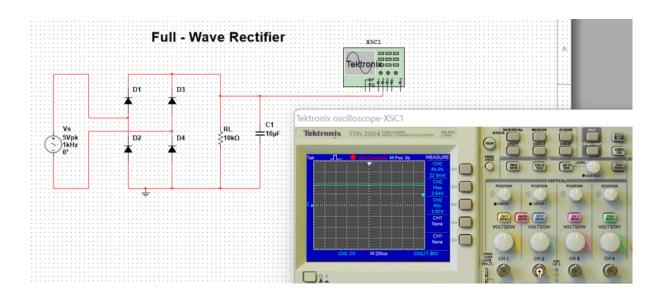

Fig: Full wave rectifier

Experimental data table:

	Half Wave Rectifier	Full wave Rectifier
V _{out} (without capacitor)	4.34V	3.71V
Vout (with 0.22 μF capacitor)	4.67V	3.93V
Vout (with 10 μF capacitor)	4.35V	3.61V

Question & Answer:

2. Ans: Shown in the simulation.

- **3. Ans:** Frequency of DC output will be directly proportional to the input frequency with or without a capacitor
- **4. Ans:** A Signal creates a ripple effect. A capacitor helps to reduce the ripples in the circuit. The capacitor is preferable to filter out the power.

<u>Discussion:</u> When we use $0.22\mu F$ capacitor in half wave rectifier. The negative half cycle clipped off. And it starts discharging. When We use $10\mu F$ so, $\tau=RC$ If the value of C increases, the time constant increases. And it holds the voltage more.

And if we increase the frequency to 100hz. Ripple will be increased. For 1khz frequency ripple will decrease For 10 khz frequency ripple will decrease more than 1khz And 100 hz ripple will increase.
